(Received 5 August 2005; published 17 May 2006)

We report an observation of the decay $B_s^0 \rightarrow D_s^- \pi^+$ in $p\bar{p}$ collisions at $\sqrt{s} = 1.96$ TeV using 115 pb^{-1} of data collected by the CDF II detector at the Fermilab Tevatron. We observe $83 \pm 11(\text{stat})$ $B_s^0 \rightarrow D_s^- \pi^+$ candidates, representing a large increase in statistics over previous measurements and the first observation of this decay at a $p\bar{p}$ collider. We present the first measurement of the relative branching fraction $\mathcal{B}(B_s^0 \rightarrow D_s^- \pi^+)/\mathcal{B}(B^0 \rightarrow D^- \pi^+) = 1.32 \pm 0.18(\text{stat}) \pm 0.38(\text{syst})$. We also measure $\mathcal{B}(B^+ \rightarrow \bar{D}^0 \pi^+)/\mathcal{B}(B^0 \rightarrow D^- \pi^+) = 1.97 \pm 0.10(\text{stat}) \pm 0.21(\text{syst})$, which is consistent with previous measurements.

B_s^0 - $\bar{B}_s^0$ oscillation is expected to occur in the standard model of particle physics. Measurement of the oscillation frequency, when combined with that for B^0 - $\bar{B}^0$ oscillation, tests the unitarity of the Cabibbo-Kobayashi-Maskawa (CKM) quark mixing matrix. A deviation from unitarity could arise from a variety of new physics effects [1]. B_s^0 meson oscillations have yet to be directly observed, with a lower limit (95% C.L.) on the oscillation frequency cur-

rently at 14.5 ps^{-1} [2]. For comparison, the average B meson lifetime is of the order of 1 ps, and the B^0 oscillation frequency is 0.5 ps^{-1} . This lower limit implies that excellent proper time resolution is required to observe the oscillation. In semileptonic B_s^0 decays, the proper time measurement is degraded due to the undetected neutrino. Fully reconstructed hadronic B_s^0 decays such as $B_s^0 \rightarrow D_s^- \pi^+$ do not suffer from this problem [3]. Obtaining a

large sample of such decays is an important first step toward measuring B_s^0 mixing.

In addition, the measurement of the branching ratio of $B_s^0 \rightarrow D_s^- \pi^+$ decay along with that of $B^0 \rightarrow D^- \pi^+$ and $B^+ \rightarrow \bar{D}^0 \pi^+$ can be used to study B meson decay mechanisms. As shown in Fig. 1, $B_s^0 \rightarrow D_s^- \pi^+$ decay proceeds only at tree level while the B^0 and B^+ modes have additional, nontree, contributions. Therefore, measurements of ratios of branching fractions of these decays can, in principle, isolate contributions from the different decay diagrams [4].

To date, a few $B_s^0 \rightarrow D_s^- \pi^+$ events have been observed [5,6] in e^+e^- collisions at LEP. B factories, while running at the $\Upsilon(4S)$ resonance, do not produce B_s^0 mesons. However, large samples of B_s^0 are produced at the Tevatron. The ability to trigger on displaced vertices allows the upgraded collider detector at Fermilab (CDF II) to collect large samples of fully reconstructed B_s^0 decay modes.

In this Letter, we present an observation of $B_s^0 \rightarrow D_s^- \pi^+$ decays and a measurement of the ratios of branching fractions of $B_s^0 \rightarrow D_s^- \pi^+$ and $B^+ \rightarrow \bar{D}^0 \pi^+$ relative to the branching fraction of $B^0 \rightarrow D^- \pi^+$ decays. We use a sample of fully reconstructed $B \rightarrow D\pi$ decays corresponding to 115 pb^{-1} of $p\bar{p}$ collisions at $\sqrt{s} = 1.96 \text{ TeV}$ collected by the CDF II detector at the Fermilab Tevatron between February 2002 and January 2003. Charge conjugate modes are implied throughout this Letter.

The components of the CDF II detector relevant to this analysis are described briefly below; a more complete description can be found elsewhere [7]. We use tracks reconstructed by both the central outer tracker (COT) and the silicon microstrip detector (SVX II) in the range $|\eta| \leq 1$ [8], where η is the pseudorapidity defined as $\eta = -\ln \tan(\theta/2)$ and θ is the polar angle with respect to the proton beam direction. The SVX II detector consists of double-sided silicon strip sensors arranged in five cylindrical shells with radii between 2.5 and 10.6 cm [9]. Surrounding the SVX II is the COT [10], an open-cell drift chamber that has an inner (outer) radius of 40 (137) cm. The COT has 96 layers, organized in 8 superlayers with alternating superlayers of axial and $\pm 2^\circ$ stereo readout. The B decays used in this analysis are selected with a three-level trigger system. At Level 1, charged tracks are reconstructed in the COT axial superlayers by a hardware processor, the eXtremely fast tracker (XFT) [11]. This trigger

requires two oppositely charged tracks with transverse momenta $p_T \geq 2 \text{ GeV}/c$ and scalar sum $p_{T1} + p_{T2} \geq 5.5 \text{ GeV}/c$. At Level 2, the silicon vertex trigger (SVT) [12] associates SVX II $r - \varphi$ position measurements with XFT tracks. This provides a precise measurement of the track impact parameter, d_0 , which is defined as the projection of a track's distance of closest approach to the beam line onto the transverse plane. The resolution of the impact parameter measurement is $50 \mu\text{m}$, which includes approximately $30 \mu\text{m}$ contribution from the transverse beam size. Hadronic decays of heavy flavor particles are selected by requiring two tracks with $120 \mu\text{m} \leq d_0 \leq 1000 \mu\text{m}$. The two trigger tracks must have an opening angle in the transverse plane satisfying $2^\circ \leq |\Delta\varphi| \leq 90^\circ$ and must satisfy the requirement $L_{xy} > 200 \mu\text{m}$, where L_{xy} is defined as the distance in the transverse plane from the beam line to the two-track vertex projected onto the two-track momentum vector. A complete event reconstruction is performed at Level 3, and the Level 1 and Level 2 requirements are confirmed. Since events satisfying the displaced vertex trigger are dominated by the decays of promptly produced charm, the largest background to $B \rightarrow D\pi$ decays results from combining a prompt D meson with an unrelated track from the event.

Reconstruction of B meson candidates begins by selecting D meson candidates. We reconstruct the following D meson decay modes: $\bar{D}^0 \rightarrow K^+ \pi^-$, $D^- \rightarrow K^+ \pi^- \pi^-$ and $D_s^- \rightarrow \phi \pi^-$ followed by $\phi \rightarrow K^+ K^-$. We exploit the narrow $\phi \rightarrow K^+ K^-$ resonance in the D_s^- decays to greatly suppress background by requiring $1010 \text{ MeV}/c^2 < m(K^+ K^-) < 1028 \text{ MeV}/c^2$. No particle identification is used in this analysis. All particle hypotheses consistent with the candidate decay structure are attempted. The track combinations which comprise a D meson candidate are required to originate from a common vertex. An additional track with $p_T > 1.6 \text{ GeV}/c$ and $\Delta R(D, \pi_B) < 1.5$ is added and assigned a pion mass to reconstruct the B meson candidate. We define $\Delta R = \sqrt{\Delta\eta^2 + \Delta\varphi^2}$, where $\Delta\varphi$ and $\Delta\eta$ are the azimuthal angle and pseudorapidity of the pion with respect to the direction of the D meson candidate. The selection requirements are optimized to yield the largest $S/\sqrt{S+B}$ for each of the decays. In the optimization procedure, the number of signal events (S) is estimated using a Monte Carlo simulation, while the number of background events (B) is estimated using sidebands of the B meson mass spectra reconstructed in data.

We require the B meson candidate tracks to be consistent with the following constraints: the D meson tracks originate from a common vertex, the momentum of the D meson points back, in three dimensions, to the remaining B meson candidate track, and the invariant mass of the D meson decay products is consistent with the world average of the corresponding D meson mass [2]. We also require that at least two of the B meson daughter tracks are consistent with the trigger requirements. The combinatorial

FIG. 1. Different Feynman diagrams which contribute to $B \rightarrow D\pi$ decays.

background is strongly reduced by requiring that $L_{xy}^B > 400 \mu\text{m}$ and $L_{xy}(B \rightarrow D) > -150 \mu\text{m}$, where the latter refers to the L_{xy} of the D meson decay vertex with respect to the B meson decay vertex. The impact parameter of the B meson momentum with respect to the beam axis is required to be less than $80 \mu\text{m}$ to assure that the B meson candidate originates from the primary vertex. The invariant mass distributions of B_s^0 , B^+ , and B^0 meson candidates are shown in Fig. 2. The prominent peak at each expected B meson mass establishes $B \rightarrow D\pi$ decay signals, including our observation of $B_s^0 \rightarrow D_s^- \pi^+$.

We measure the following ratio:

$$\frac{\mathcal{B}(B_s^0 \rightarrow D_s^- \pi^+)}{\mathcal{B}(B^0 \rightarrow D^- \pi^+)} = \frac{N(B_s^0)}{N(B^0)} \frac{\epsilon(B^0)}{\epsilon(B_s^0)} \frac{f_d}{f_s} \times \frac{\mathcal{B}(D^- \rightarrow K^+ \pi^- \pi^-)}{\mathcal{B}(D_s^- \rightarrow \phi \pi^-) \mathcal{B}(\phi \rightarrow K^+ K^-)} \quad (1)$$

where $N(B_s^0)$ and $N(B^0)$ are the signal yields, f_d/f_s is the ratio of fragmentation fractions for B^0 and B_s^0 mesons, and $\epsilon(B^0)/\epsilon(B_s^0)$ is the ratio of trigger and reconstruction efficiencies. Equation (1) also applies to the $B^+ \rightarrow \bar{D}^0 \pi^+$ mode, with terms for B_s^0 decays replaced by those relevant

to B^+ decays. There are three components to the ratio of branching fractions measurement: the ratio of B meson yields obtained from fits to the invariant mass spectra, the ratio of signal efficiencies obtained from Monte Carlo simulation, and the product of previously measured production and branching fractions.

In our analysis, we use Monte Carlo simulation to determine shapes of mass spectra and relative efficiencies. The Monte Carlo generation proceeds as follows. Transverse momentum and rapidity distributions of single b quarks are generated based on calculations using next-to-leading-order perturbative QCD [13]. B meson kinematic distributions are obtained by simulating Peterson fragmentation [14] on quark-level distributions. Additional fragmentation particles, correlated $b\bar{b}$ production and the underlying event structure are not simulated. B meson decays are simulated using EvtGen [15]. The simulation of the CDF II detector and trigger is based upon a GEANT 3 description [16] that includes effects of time variation of the beam position and hardware configuration of the SVX II and SVT.

The yield of B mesons is extracted from the invariant mass spectra using a binned χ^2 fit, as shown in Fig. 2. There are three contributions to the background shape used in the fit. The combinatorial background component is modeled with a linear combination of a linear and exponential distribution. The shape of background due to Cabibbo-suppressed $B \rightarrow DK$ decay is modeled by a Gaussian and is shown as shaded distributions in Figs. 2(a)–2(c). Backgrounds due to partially reconstructed B decays contribute to the low mass side of the signal peak and are modeled by inclusive $B \rightarrow DX$ Monte Carlo simulation. The structures in the region close to the signal are due to $B \rightarrow D^* \pi$ decays, where a photon or a π^0 from the D^* decay is not reconstructed. The decay of the polarized D^* produces the double-peaked structure. As an example of the various contributing backgrounds, Fig. 2(d) shows the invariant mass spectrum for $B \rightarrow DX$ Monte Carlo reconstructed as $B^+ \rightarrow \bar{D}^0 \pi^+$. In the fit to the data mass spectrum, the fractions of combinatorial background and partially reconstructed B 's are allowed to float in the fit. The ratio of Cabibbo-suppressed $B \rightarrow DK$ background to the corresponding signal is fixed to the world average ratio of branching fractions, with the trigger and reconstruction efficiencies of the two modes taken into account. The fitted yields of $B^0 \rightarrow D^- \pi^+$, $B^+ \rightarrow \bar{D}^0 \pi^+$, and $B_s^0 \rightarrow D_s^- \pi^+$ decays are $1118 \pm 43(\text{stat})$, $1260 \pm 42(\text{stat})$ and $83 \pm 11(\text{stat})$ events, respectively.

Trigger and reconstruction efficiencies for B^0 , B^+ , and B_s^0 decays are determined using Monte Carlo simulation. The trigger efficiency differs among the three B meson decay modes due to differences in decay kinematics (e.g., opening angle distributions) which arise from the different masses and spins of the intermediate and final state particles. The ratios of efficiencies are

FIG. 2 (color online). Invariant mass spectra for (a) $D_s^- \pi^+$, (b) $D^- \pi^+$, and (c) $\bar{D}^0 \pi^+$ for data, with χ^2 fits overlaid. The main background under the signal peak is combinatorial, modeled with a combination of a linear and exponential function. The shaded peak corresponds to $B \rightarrow DK$ decays, and is modeled with a Gaussian. The additional background component in the low mass region is due to partially reconstructed B decays. This background component is modeled using shapes determined by inclusive $B \rightarrow DX$ Monte Carlo simulations. A sample Monte Carlo mass distribution for $B^+ \rightarrow \bar{D}^0 \pi^+$ events is shown in (d). Contributions from different sources in (d) are ordered by peak position, from right to left.

$\epsilon(B^0)/\epsilon(B^+) = 0.708 \pm 0.010$ and $\epsilon(B^0)/\epsilon(B_s^0) = 0.903 \pm 0.012$, where the uncertainties are due to the limited statistics of Monte Carlo samples.

World average values [2] are used for the various branching fractions in Eq. (1). In terms of B meson production, we assume $f_d = f_u$, consistent with previous measurement [17]. The B_s^0/B^0 production fraction used in this analysis is the world average value, $f_s/f_d = 0.270 \pm 0.029$, currently dominated by LEP measurements. The ratio of fragmentation fractions may be different in a hadron collider environment than in e^+e^- collisions. However, the ratio of fragmentation fractions measured by CDF [17] is consistent with the LEP results.

Many systematic uncertainties cancel in the measurement of ratios of branching fractions due to the similarity of final state kinematics. Systematic uncertainties come from three main sources: fitting the invariant mass distributions to obtain signal yields, determination of the ratio of efficiencies, and uncertainties on external inputs. The contribution to the systematic uncertainty from externally measured quantities is calculated by propagating world average uncertainties. Systematic uncertainties on the signal yields are determined by comparing the fitted yields after changing the invariant mass region of the fit and varying the background shape within the range allowed by the $B \rightarrow DX$ Monte Carlo statistics and world average uncertainties on the branching fractions of participating B decays. Systematic uncertainties on the ratio of efficiencies come from physics sources such as the choice of p_T spectrum or meson lifetime, and detector sources such as inaccuracies in the XFT and SVT hardware simulation. The uncertainty due to a given source is estimated by the shift of the ratio of efficiencies when the effect of that source is modified in the Monte Carlo simulation. The effect of the choice of B meson p_T spectrum is estimated by reweighting the Monte Carlo simulation to match the measured B hadron p_T spectrum [7]. Since the trigger and

analysis selection only accept events in which the B meson is displaced from the primary interaction point, the efficiencies depend upon the B and D meson lifetimes. To estimate uncertainties due to B and D meson lifetimes, the Monte Carlo simulation is reweighted with different lifetimes within the world average uncertainties. Because of the different specific ionization of $\pi^\pm$ and $K^\pm$ in the COT, kaons are 6% less efficient in satisfying the XFT requirements [18]. The Monte Carlo simulation is reweighted to reproduce this effect. To estimate the uncertainty due to imperfections in simulating the signal selection requirement efficiencies, we compare efficiencies between Monte Carlo simulation and sideband subtracted B^+ and B^0 signal for every selection requirement separately. In the case of the B^+/B^0 branching fraction ratio measurement, there is an additional systematic uncertainty associated with the fact that the B^0 decay has four tracks in the final state while B^+ has only three. We infer the corrections and systematic uncertainties due to the fourth track by comparing trigger and reconstruction efficiencies in data and Monte Carlo simulations for semileptonic $B \rightarrow D^{*-}l^+X$, $D^{*-} \rightarrow \bar{D}^0\pi^-$ decays between the $\bar{D}^0 \rightarrow K^+\pi^-$ and $K^+\pi^-\pi^+\pi^-$ final states.

The systematic uncertainties are summarized in Table I. The total systematic uncertainty is obtained by adding individual contributions in quadrature. Using Eq. (1), we obtain the following values for the ratios of branching fractions:

$$\frac{\mathcal{B}(B_s^0 \rightarrow D_s^- \pi^+)}{\mathcal{B}(B^0 \rightarrow D^- \pi^+)} = 1.32 \pm 0.18(\text{stat}) \pm 0.10(\text{syst}) \pm 0.34(\text{BR}) \pm 0.14(\text{PR}), \quad (2)$$

$$\frac{\mathcal{B}(B^+ \rightarrow \bar{D}^0 \pi^+)}{\mathcal{B}(B^0 \rightarrow D^- \pi^+)} = 1.97 \pm 0.10(\text{stat}) \pm 0.15(\text{syst}) \pm 0.14(\text{BR}), \quad (3)$$

where BR and PR refer to the uncertainty on the ratio of D meson branching fractions and B_s^0 meson production relative to B^0 , respectively. Under the assumption of isospin invariance, our measurement of the ratio $\mathcal{B}(B^+ \rightarrow \bar{D}^0 \pi^+)/\mathcal{B}(B^0 \rightarrow D^- \pi^+)$ is consistent with the world average [2]. This provides a high statistics cross-check of the measurement procedure.

In conclusion, we have presented the first observation of $B_s^0 \rightarrow D_s^- \pi^+$ decays in $p\bar{p}$ collisions, and the first measurement of the $B_s^0 \rightarrow D_s^- \pi^+$ branching fraction relative to the $B^0 \rightarrow D^- \pi^+$ branching fraction. The precision of this measurement is currently not adequate to separate the contributions of different decay diagrams [4]. We expect the measurement precision to improve as world average values of D meson branching fractions and B meson production fractions improve.

We thank the Fermilab staff and the technical staffs of the participating institutions for their vital contributions.

TABLE I. Summary of relative systematic uncertainties.

Effect	B_s^0/B^0 [%]	B^+/B^0 [%]
fit $N(B_s^0, B^+)$	4.5	2.0
fit $N(B^0)$	2.3	2.3
B_{pT} spectrum	2.6	1.5
trigger simulation	1.6	0.2
selection simulation	4.0	4.0
ϕ^0 mass cut	0.2	not applicable
B^+/B_s^0 meson lifetime	2.0	0.4
D^0/D_s^- meson lifetime	0.1	0.1
B^0 meson lifetime	0.4	0.4
D^- meson lifetime	<0.1	<0.1
fourth track accept	not applicable	5.2
Total	7.4	7.4
